(57) **ABSTRACT**

A portable computing device is disclosed. The portable computing device can take many forms such as a laptop computer, a tablet computer, and so on. The portable computing device can include at least a single piece housing. The single piece housing including a plurality of steps. The plurality of mounting steps are formed by at least removing a preselected amount of housing material at predetermined locations on the interior surface. At least some of the mounting steps are used to mount at least some of the plurality of internal operating components to the housing.

COMPONENT ASSEMBLY**CROSS REFERENCE TO RELATED APPLICATIONS**

This U.S. patent application is a continuation of co-pending U.S. application Ser. No. 12/694,200 filed Jan. 26, 2010 and entitled "COMPONENT ASSEMBLY" and claims priority under 35 U.S.C. §119(e) to U.S. Provisional Patent Application Ser. No. 61/292,739 entitled "HANDHELD COMPUTING DEVICE" by Ternus et al. filed Jan. 6, 2010 which is incorporated by reference in its entirety for all purposes.

This patent application is related to and incorporates by reference in their entirety the following co-pending patent applications:

- (i) U.S. patent application Ser. No. 12/694,162 entitled "ASSEMBLY OF A DISPLAY MODULE" by Ternus et al. filed Jan. 26, 2010;
- (ii) U.S. patent application Ser. No. 12/694,085 entitled "HANDHELD COMPUTING DEVICE" by Ternus et al. filed Jan. 26, 2010;
- (iii) U.S. patent application Ser. No. 12/694,168 entitled "DISPLAY MODULE" by McClure et al. filed Jan. 26, 2010;
- (iv) U.S. patent application Ser. No. 12/694,166 entitled "PRINTED CIRCUIT BOARD" by McClure et al. filed Jan. 26, 2010; and
- (v) U.S. patent application Ser. No. 12/694,083; and entitled "EDGE BREAK DETAILS AND PROCESSING" by Sweet et al. filed Jan. 26, 2010 that is, in turn, a continuation in part of U.S. patent application Ser. No. 12/580,934 entitled "METHOD AND APPARATUS FOR POLISHING A CURVED EDGE" by Lancaster et al. filed Oct. 16, 2009 that takes priority under 35 U.S.C. 119(e) to U.S. Provisional Patent Application Ser. No. 61/249,200 entitled "COMPLEX GEOGRAPHICAL EDGE POLISHING" by Johannessen filed Oct. 6, 2009.

BACKGROUND**1. Field of the Described Embodiments**

The described embodiments relate generally to portable computing devices such as laptop computers, tablet computers, and the like. More particularly, enclosures of portable computing devices and methods of assembling portable computing devices are described.

2. Description of the Related Art

In recent years, portable computing devices such as laptops, PDAs, media players, cellular phones, etc., have become small, light and powerful. One factor contributing to this reduction in size can be attributed to the manufacturer's ability to fabricate various components of these devices in smaller and smaller sizes while in most cases increasing the power and/or operating speed of such components. The trend of smaller, lighter and powerful presents a continuing design challenge in the design of some components of the portable computing devices.

One design challenge associated with the portable computing device is the design of the enclosures used to house the various internal components. This design challenge generally arises from a number of conflicting design goals that includes the desirability of making the enclosure lighter and thinner, the desirability of making the enclosure stronger and making the enclosure more esthetically pleasing. The lighter enclosures, which typically use thinner plastic structures and fewer fasteners, tend to be more flexible and therefore they

have a greater propensity to buckle and bow when used while the stronger and more rigid enclosures, which typically use thicker plastic structures and more fasteners, tend to be thicker and carry more weight. Unfortunately, however, the increased weight consistent with the more rugged enclosure can lead to user dissatisfaction whereas bowing of enclosures formed of lightweight material can result in damaging some of the internal components (such as printed circuit boards) of the portable device.

Furthermore, the enclosures are mechanical assemblies having multiple parts that are screwed, bolted, riveted, or otherwise fastened together at discrete points. These assembly techniques typically complicate the housing design and create aesthetic difficulties because of undesirable cracks, seams, gaps or breaks at the mating surfaces and fasteners located along the surfaces of the housing. For example, a mating line surrounding the entire enclosure is produced when using an upper and lower casing. Moreover, the various components and complicated processes used to manufacture the portable device can make assembly a time consuming and cumbersome process requiring, for example, a highly trained assembly operator working with special tools.

Another challenge is related to techniques for mounting structures within the portable computing devices. Conventionally, the structures have been laid over one of the casings (upper or lower) and attached to one of the casings with fasteners such as screws, bolts, rivets, etc. That is, the structures are positioned in a sandwich like manner in layers over the casing and thereafter fastened to the casing. This methodology suffers from the same drawbacks as mentioned above, i.e., assembly is a time consuming and cumbersome process.

In view of the foregoing, there is a need for improved component density and associated assembly techniques that reduce cost and improve outgoing quality. In addition, there is a need for improvements in the manner in which handheld devices are assembled such as improvements that enable structures to be quickly and easily installed within the enclosure. It is also desirable to minimize the Z stack height of the assembled components in order to reduce the overall thickness of the portable computing device and thereby improve the overall aesthetic look and feel of the product.

SUMMARY OF THE DESCRIBED EMBODIMENTS

A portable computing device is disclosed. The portable computing device can take many forms such as a laptop computer, a tablet computer, and so on. In one embodiment, the portable computing device can include a single piece housing having a front opening. In the described embodiment, the single piece housing can, in turn, include an integral bottom and side walls that cooperate to form a cavity in cooperation with the front opening where an interior surface of the bottom wall is curved and includes a plurality of machined steps suitable for mounting an internal component thereon where at least some of the machined steps form a pattern of steps. In addition to the single piece housing, the portable computing device can include a component mounted directly to the curved bottom wall. The component, in turn, includes a mounting feature having a shape that conforms to the pattern of steps such that the mounting feature is directly mounted to the bottom wall of the single piece housing without conforming to the curvature of the bottom wall.

3

In one aspect, the steps can be machined in one set up using computer numerical controlled (CNC) machine tools and associated techniques. In addition, any sharp edges can be rounded to a more benign shape thereby reducing any possibility of damaging internal components.

In another embodiment, a button assembly is described. The button assembly can include at least a button body having an external top surface configured to be pressed by a user, at least one tactile switch unit, mounted on a top surface of a first printed circuit board positioned such that a bottom surface of the button body can contact the tactile switch unit when the top surface of the button body is pressed by the user, and a plurality of conductive posts mounted on a top surface of a second printed circuit board positioned and connected to a bottom surface of the first printed circuit board through a plurality of conductive pads mounted thereon. In the described embodiment, when a current passes through at least two of the plurality of conductive posts when the user presses the external top surface of the button body thereby closing a circuit in the tactile switch unit.

In another embodiment, a button assembly is described that includes at least a button body including an exterior surface and at least one post extending from a interior surface opposite the exterior surface, the at least one post having a stem portion proximal to the interior surface and a capture portion distal to the interior surface, the capture portion having a diameter greater than the stem portion, a structural support section having a first opening wider than the capture portion of the post of the button body and configured to provide structural stability to a section of a housing to which the structural support section is mounted, the section of the housing having a second opening larger than the exterior surface of the button body, and a retention bracket having a third opening wider than the diameter of the stem portion and narrower than the diameter of the capture portion of the post. In the described embodiment, the button assembly can be at least partially assembled by extending the post of the button body through the second opening in the housing and the first opening in the structural support section and retained in position by the retention bracket.

In still another embodiment, a method is described. The method can be carried out by receiving a housing having a cavity for receiving internal components, the housing having a plurality of mounting steps formed on a curved interior bottom surface of the housing. A component to be mounted to the housing is then received, the component having a conformally shaped mounting feature. The conformally shaped mounting feature is then placed in contact with at least one of the mounting steps and bonded to the bottom surface of the housing. In this way, the mounting feature is directly mounted to the bottom wall of the single piece housing without conforming to the curvature of the bottom wall.

In one aspect, an integrated beam system can be formed by removing less than the determined amounts of material from an inner surface of the housing. The integrated beam system can be part of the housing and be used to provide support for the housing by, in part, distributing a force applied to the portable computing device. In this way, by distributing the applied force, the risk of deforming or damaging the housing can be substantially reduced.

BRIEF DESCRIPTION OF THE DRAWINGS

The embodiments will be readily understood by the following detailed description in conjunction with the

4

accompanying drawings, wherein like reference numerals designate like structural elements, and in which:

FIG. 1A shows a top view of a portable computing device in accordance with the described embodiments.

FIG. 1B shows a perspective top view of a portable computing device in accordance with the described embodiments.

FIG. 2A shows a full interior view of a housing suitable for enclosing operational components of the portable computing device shown in FIGS. 1A and 1B.

FIG. 2B shows a perspective interior view of a housing suitable for enclosing operational components of the portable computing device shown in FIGS. 1A and 1B.

FIGS. 2C and 2D show representative cross sectional view of section A-A of the housing shown in FIG. 2A.

FIG. 3 presents a top level internal view of portable computing device showing a specific arrangement of various internal components.

FIG. 4A shows an exploded view of battery assembly in accordance with the described embodiments.

FIG. 4B shows a close up view of battery frame shown in FIG. 4A.

FIG. 5 shows cross section along line AA of FIG. 3.

FIG. 6 shows a representative cross section of logo in accordance with the described embodiments.

FIG. 7 shows exploded view of integrated audio module in accordance with the described embodiments.

FIG. 8A illustrates a cross-sectional perspective view of a button assembly mounted through a cover glass of a portable computing device in accordance with the described embodiments.

FIG. 8B illustrates a second cross-sectional view of the button assembly mounted in the portable computing device shown in FIG. 8A.

FIG. 8C illustrates a top view of a portion of the button assembly of FIG. 8A.

FIG. 8D illustrates a simplified cross-sectional view through a portion of the button assembly of FIG. 8A.

FIG. 9A presents a perspective internal view of a reinforced housing of a portable computing device in the region of a button assembly.

FIG. 9B presents a perspective external view of the reinforced housing of the portable computing device illustrated in FIG. 9A.

FIG. 9C illustrates an exploded perspective internal view of a button assembly mountable through the reinforced housing **102** of the portable computing device **100** illustrated in FIGS. 9A-B.

FIG. 9D illustrates an exploded perspective external view of the button assembly illustrated in FIGS. 9A-C.

FIG. 9E shows a simplified horizontal cross-sectional view of a portion of the button assembly illustrated in FIGS. 9A-D.

FIG. 10 shows a flowchart detailing a process in accordance with the described embodiments.

FIG. 11 shows SIM card in accordance with the described embodiments.

FIG. 12 shows SIM card of FIG. 11 incorporated into portable computing device.

DESCRIBED EMBODIMENTS

In the following paper, numerous specific details are set forth to provide a thorough understanding of the concepts underlying the described embodiments. It will be apparent, however, to one skilled in the art that the described embodiments may be practiced without some or all of these specific

details. In other instances, well known process steps have not been described in detail in order to avoid unnecessarily obscuring the underlying concepts.

This paper discusses an aesthetically pleasing portable computing device that is easy to carry with one hand and operate with the other. The portable computing device can be formed of a single piece seamless housing and an aesthetically pleasing protective top layer that can be formed of any of a number of durable and strong yet transparent materials such as highly polished glass or plastic. For the remainder of this discussion, however, the protective top layer can take the form of highly polished cover glass without any loss in generality. Furthermore, the uniformity of the appearance of the portable computing device can be enhanced since (unlike conventional portable computing devices) the cover glass can be mounted to the single piece seamless housing without the use of a bezel. This simplicity of design can accrue many advantages to the portable computing device besides those related to aesthetic look and feel. For example, fewer components and less time and effort can be required for assembly of the portable computing device, and the absence of seams in the single piece housing can provide good protection against environmental contamination of internal components. Moreover, the ability of the portable computing device to successfully withstand applied loads (such as from day to day use) as well as those from less frequent but potentially more damaging events such as being dropped can be substantially improved over conventional portable computing devices.

In the described embodiments, the single piece seamless housing can be formed from plastic or metal. In the case where the single piece seamless housing is formed of metal, the metal can take the form of a single sheet (such as aluminum). The single sheet of metal can be formed into a shape appropriate for housing various internal components as well as providing various openings into which switches, connectors, displays, and so on can be accommodated. The single piece seamless housing can be forged, molded, or otherwise processed into a desired shape. The shape of the housing can be asymmetric in that an upper portion of the housing can be formed to have a substantially different shape than that exhibited by a lower portion of the housing. For example, the upper portion of the housing can have surfaces that meet at distinct angles forming well defined boundary whereas the lower portion can be formed to have a surface with a spline shape. The transition zone between the upper portion having distinct edges and the lower, spline shaped portion can take the form of an edge having a rounded shape providing both a natural change from the upper portion of the housing (i.e., the area of distinct edges) and the smoother surface presented by the lower portion of the housing. It should also be noted that in addition to providing a more aesthetically pleasing transition, the rounded shape of the edge in the transition zone can provide a more comfortable feel when being held in a user's hand either during use or merely being carried about. One of the advantages to using metal for the housing is ability of metal to provide good electrical grounding for any internal components requiring a good ground plane. For example, performance of a built in RF antenna can be substantially improved when a good ground plane is provided. Moreover, a good ground plane can be used to help mitigate the deleterious effects caused by, for example, of electromagnetic interference (EMI) and/or electrostatic discharge (ESD).

It should be noted that throughout the following discussion, the term "CNC" is used. The abbreviation CNC stands for computer numerical control and refers specifically to a

computer controller that reads computer instructions and drives a machine tool (a powered mechanical device typically used to fabricate components by the selective removal of material). It should be noted however, that any appropriate machining operation can be used to implement the described embodiments and is not strictly limited to those practices associated with CNC.

These and other embodiments are discussed below with reference to FIGS. 1-xx. However, those skilled in the art will readily appreciate that the detailed description given herein with respect to these figures is for explanatory purposes only and should not be construed as limiting.

FIG. 1A illustrates a specific embodiment of portable computing device 100. More specifically, FIG. 1A shows a full top view of fully assembled portable computing device 100. Portable computing device 100 can process data and more particularly media data such as audio, video, images, etc. By way of example, portable computing device 100 can generally correspond to a device that can perform as a music player, game player, video player, personal digital assistant (PDA), tablet computer and/or the like. With regards to being handheld, portable computing device 100 can be held in one hand by a user while being operated by the user's other hand (i.e., no reference surface such as a desktop is needed). For example, the user can hold portable computing device 100 in one hand and operate portable computing device 100 with the other hand by, for example, operating a volume switch, a hold switch, or by providing inputs to a touch sensitive surface such as a display or pad.

Portable computing device 100 can include single piece seamless housing 102 that can be formed of any number of materials such as plastic or metal which can be forged, molded, or otherwise processed into a desired shape. In those cases where portable computing device 100 has a metal housing and incorporates RF based functionality, it may be advantageous to provide at least a portion of housing 102 in the form of radio (or RF) transparent materials such as ceramic, or plastic. In any case, housing 102 can be configured to at least partially enclose any suitable number of internal components associated with the portable computing device 100. For example, housing 102 can enclose and support internally various structural and electrical components (including integrated circuit chips and other circuitry) to provide computing operations for portable computing device 100. The integrated circuits can take the form of chips, chip sets, modules any of which can be surface mounted to a printed circuit board, or PCB, or other support structure. For example, a main logic board (MLB) can have integrated circuits mounted thereon that can include at least a microprocessor, semi-conductor (such as FLASH) memory, various support circuits and so on.

Housing 102 can include opening 104 for placing internal components and may be sized to accommodate a display assembly or system suitable for providing a user with at least visual content as for example via a display. In some cases, the display system can include touch sensitive capabilities providing the user with the ability to provide tactile inputs to portable computing device 100 using touch inputs. The display system can be formed of a number of layers including a topmost layer taking the form of transparent protective layer 106 formed of polycarbonate or other appropriate plastic or highly polished glass. Using highly polished glass, protective layer 106 can take the form of cover glass 106 substantially filling opening 104. Seal 108 can be used to form a gasket between cover glass 106 and housing 102. Seal 108 can be formed of a resilient material such as a plastic along the lines of thermoplastic urethane or TPU. In

this way, seal **108** can provide protection against environmental contaminants from entering the interior of portable computing device **100**. Racetrack **110** can be defined as the uppermost portion of the housing **102** that surrounds cover glass layer **106**. In order to maintain the desired aesthetic look and feel of portable computing device **100**, it is desirable that any offsets between the housing **102** and cover glass **106** be minimized by centering racetrack **110**.

Although not shown, the display panel underlying cover glass **106** can be used to display images using any suitable display technology, such as LCD, LED, OLED, electronic or e-inks, and so on. Display assembly may be placed and secured within the cavity using a variety of mechanisms. In one embodiment, the display system is snapped into the cavity. It may be placed flush with the adjacent portion of the housing. In this way, the display can present visual content that can include video, still images, as well as icons such as graphical user interface (GUI) that can provide information the user (e.g., text, objects, graphics) as well as receive user provided inputs. In some cases, displayed icons can be moved by a user to a more convenient location on the display. For example, GUI can be moved by the user manually dragging GUI from one location to a more convenient location. The display can also provide a user with tactile feedback provided by a number of haptic actuators usually, but not always, arranged in an array of haptic actuators incorporated into the display. In this way, the haptic actuators can provide the user with tactile feedback.

In some embodiments, a display mask (not shown) can be applied to, or incorporated within or under cover glass **106**. The display mask can be used to accent an unmasked portion of the display used to present visual content. The display mask can be used to make less obvious home button **112** used to provide a specific input such as change display mode, for example to portable computing device **100**. The display mask can render home button **112** less obvious by, for example, being closer in tone or color to home button **112**. For example, if home button **112** is formed of a material that is somewhat darker (such as gray or black) than cover glass **106**, then using a similarly colored display mask can reduce the visual impact of home button **112** when compared with the unmasked portion of cover glass **106**. In this way, the visual impact of home button **112** can be reduced by being integrated into the overall look of the display mask. Furthermore, the display mask can provide a natural mechanism for directing the attention of a viewer to the unmasked area of the display used to present visual content.

Portable computing device **100** can include a number of mechanical controls for controlling or otherwise modifying certain functions of portable computing device **100**. For example, power switch **114** can be used to manually power on or power off portable computing device **100**. Mute button **116** can be used to mute any audio output provided by portable computing device **100** whereas volume switch **118** can be used to increase/decrease volume of the audio output by portable computing device **100**. It should be noted that each of the above described input mechanisms are typically disposed through an opening in housing **102** such that they can couple to internal components in some embodiments, portable computing device **100** can include a camera module configured to provide still or video images. The placement may be widely varied and may include one or more locations including for example front and back of the device, i.e., one through the back housing, the other through the display window.

Portable computing device **100** can include a mechanism for wireless communications, as either a transceiver type

device or receiver only, such as a radio, portable computing device **100** can include an antenna that can be disposed internal to a radio transparent portion of housing **102**. In some embodiments, an antenna can be incorporated into seal **108** or cover glass **106**. In other embodiments, a portion of housing **102** can be replaced with radio transparent material in the form of an antenna window described in more detail below. The radio transparent material can include, for example, plastic, ceramic, and so on. The wireless communications can be based on many different wireless protocols including for example 3G, 2G, Bluetooth, RF, 802.11, FM, AM, and so on. Any number of antennae may be used, which can use a single window or multiple windows depending on the needs of the system. In one embodiment, the system can include at least first and second antenna windows built into the housing.

FIG. 1B shows a perspective top view of portable computing device **100** in accordance with the described embodiments. As shown in FIG. 1B, portable computing device **100** can include one or more speakers **120** used to output audible sound. Portable computing device **100** can also include one or more connectors for transferring data and/or power to and from portable computing device **100**. For example, portable computing device **100** can include multiple data ports, one for each configuration of portrait mode and landscape mode. However, the currently described embodiment includes single data port **122** that can be formed of connector assembly **124** accommodated within an opening formed along a first side of housing **102**. In this way, portable computing device **100** can use data port **122** to communicate with external devices when portable computing device **100** is mounted in docking station. It should be noted that in some cases, portable computing device **100** can include an orientation sensor or an accelerometer that can sense the orientation or movement of portable computing device **100**. The sensor can then provide an appropriate signal which will then cause portable computing device **100** to present visual content in an appropriate orientation.

Connector assembly **124** can be any size deemed appropriate such as, for example, a 30 pin connector. In some cases, the connector assembly **124** can serve as both a data and power port thus obviating the need for a separate power connector. Connector assembly **124** can be widely varied. In one embodiment, connector assembly **124** can take the form of a peripheral bus connector, such as a USB or FIREWIRE connector. These types of connectors include both power and data functionality, thereby allowing both power delivery and data communications to occur between the portable computing device **100** and the host device when the portable computing device **100** is connected to the host device. In some cases, the host device can provide power to the media portable computing device **100** that can be used to operate the portable computing device **100** and/or charge a battery included therein concurrently with the operating.

FIGS. 2A and 2B present a representative interior view of cavity (also referred to as lumen) **200** of single piece seamless housing **102** used to enclose various internal components of the portable computing device **100** shown in FIGS. 1A and 1B. In the described embodiment, single piece seamless housing **102** can be formed from a single sheet of metal (such as aluminum) and formed into an appropriate shape using, for example, using conventional collapsible core metal forming techniques well known to those skilled in the art. Housing **102** can include a number of features used to facilitate the installation of internal components used in the assembly of portable computing device **100**. For example, opening **202** can be formed in housing **102** suitably

sized and located for an RF antenna. In the case where opening 202 is used for placing an RF antenna, opening 202 can support an RF antenna support assembly formed of at least some radio transparent material. In this way, the RF antenna support assembly can facilitate unimpeded transmission and reception of RF energy in support of any number of wireless protocols such as WiFi, Blue Tooth, and so on. It should be noted the ability to provide unfettered RF functionality is especially important when housing 102 is formed of radio opaque materials such as most metals.

In order to accommodate various interfaces (dock, audio jack, volume, power, mute, and so on), FIG. 2B shows how openings of various sizes can be created in the housing 102. For example, opening 204 can be used to support data port 122, openings 206 can be used to provide support for speakers 120; opening 208 can provide support for volume switch 118 and opening 210 for mute button 116. Furthermore, opening 212 can be used to provide support for power switch 114 and opening 214 for an audio jack. It should be noted that any number of approaches can be used to create these openings and make the opening trim appear to be thicker than the thickness (about 1.5 mm) of the sheet metal used to create housing 102. Creating these openings in the housing 102, however, can result in long and thin webs of metal that can deform from the impact of a drop event or cause housing 102 to exhibit unacceptable flexing under torsion. A particular reinforcing technique is described below.

A plurality of steps 216 can be formed in bottom surface 218 of housing 102. Steps 216 can be used to provide a support platform for mounting various internal components onto bottom surface 218 of housing 102. In the described embodiment, steps 216 can be formed by removing a pre-determined amount of housing material (such as aluminum) using conventional machining techniques. Typically, each of the steps can have rounded edges in order to protect internal components that may come in contact. As is apparent in FIGS. 2A and 2B, steps 216 can also be formed into various patterns, such as pattern 220, 222 and pattern 224. Far from being merely aesthetic in nature, the various patterns can be very useful. For example, the various patterns can be used to accommodate mounting structures used to support internal components, such as for example a battery frame. In some cases, pattern 226 can take the form of an integrated beam structure described in more detail below that provides for a more even distribution of loads applied to housing 102. Moreover, in addition to providing structural support and aiding in resisting deformation, the housing material removed in the formation of the plurality of steps 216 can help to substantially reduce the overall weight of housing 102.

FIGS. 2C and 2D show shows a cross sectional view of housing 102 taken along line A-A of FIGS. 2A and 2B. In particular, FIG. 2C shows the nature of the undercut geometry of housing 102 illustrating more clearly how linear dimensions (length L, for example) of opening 104 into which the operational components can be inserted during assembly is smaller than the linear dimensions (length l, for example) of the body of the housing 102. Moreover, the curvature of housing 102 can be asymmetric in that upper portion 228 of housing 102 can be formed to have distinct edges whereas lower portion 230 can be formed to have spline shape. This asymmetry aids in the tactile sensation presented by portable computing device 100 in part because it provides a better fit to the user's hand.

In any case, housing 102 can have a nominal wall thickness t_{nom} , (that can be on the order of about 1.5 mm).

Upper portion 228 can be formed in such a way as to have a substantially uniform average wall thickness close to nominal wall thickness t_{nom} . Since interior surface 218 of lower portion 230 substantially conforms to the spline shape of exterior surface of housing 102, mounting internal components onto interior surface 218 can be difficult or at best sub-optimal. For example, in order to securely place an internal component onto interior surface 218, any mounting structure used to mount the internal component to interior surface 218 would have to be specially machined to fit the curvature of interior surface 218. This special machining would require special tooling and add extra costs to manufacture as well as adding complexity and time required for assembly.

Therefore, in order provide a more suitably shaped interior surface upon which to mount internal components (as well as to reduce the weight of housing 102), interior surface 218 of housing 102 can be sculpted (using CNC machining techniques, for example) to any appropriate shape. Interior surface 218 can be sculpted to include plurality of mounting steps 216 that can resemble in form a terrace. Firstly, however, a determination can be made of a minimum thickness t_{min} for housing 102 that is consistent with both good structural integrity and a desired weight reduction. For example, in the case where housing 102 is formed of aluminum having nominal thickness t_{nom} of about 1.5 mm, it has been determined that minimum thickness t_{min} of about 0.6 mm results in an average step height "h" of about 0.5 mm resulting in an average weight reduction of about 25%. Using these settings, interior surface 218 of housing 102 can be machined in one machine set up to include a suitable number of steps each having step height h creating various terracing patterns well suited for both reducing the overall weight of housing 102 but also providing suitable mounting platforms for mounting various internal components.

Portions of interior surface 218 can be maintained at a thickness that is substantially the same as nominal thickness t_{nom} . For example, in order to distribute any stresses applied to housing 102 more evenly, integrated beam system (which in FIG. 2A pattern 226 that resembles the letter "H") can be created simply by not machining those portions of housing 102 consistent with the desired location of integrated beam system. In some cases, however, integrated beam system can be created by simply removing less material from housing 102 in those locations corresponding to integrated beam system such that thickness t corresponding to integrated beam system is $t_{nom} > t > t_{min}$. In this way, beam structure can more evenly distribute applied loads across a larger region of housing 102 thereby minimizing the likelihood of buckling or deformation.

Unlike the assembly of conventional portable electronic devices where components are assembled in a top-down manner (i.e., the components are inserted into the housing before the bezel is snapped on), the undercut geometry of housing 102 requires that all components fit within the dimensions (L, W) of opening 104. Moreover, the assembly of portable electronic device 100 can be carried out in a bottom-up manner. In order to facilitate the bottom-up assembly of portable electronic device 100 and to minimize any offsets between the polished top glass layer and an uppermost portion of the housing (racetrack 110), various techniques, apparatus and systems can be used that minimize stack (i.e., z direction) tolerance as well as to increase component density within housing 102.

The following discussion describes specific approaches to both minimizing the Z height of the assembled components and maximizing component density within housing 102. In

11

other words, the Z stack associated with installed internal components is such that the components can be easily accommodated by cavity 200 without the need to resort to lengthy and time consuming assembly procedures. The reduced Z stack and improved component density can be accomplished in many ways such as configuring the structure of an internal component to perform multiple functions. For example, portable computing device 100 can include a battery assembly. The battery assembly can, in turn, include battery cells that can be suspended from an upper protective layer leaving a gap (referred to as a swell gap) between a lower surface of housing 102 and a lower surface of the battery cells. In conventionally arranged battery assemblies, the battery cells would require space above the battery cells to accommodate swelling anticipated to occur during normal operation. However, by placing the swell gap below the battery cells, space between the battery cells and the housing that would otherwise be wasted can be used in a productive manner. Component density can also be increased. For example, circuits that would otherwise be considered separate can be combined to share a single connector. For example, an audio module can include both a microphone and associated circuitry that can share a flex connector with an audio circuit used to produce audio output. In this way, both the number and overall footprint of the internal components can be substantially reduced without adversely affecting overall functionality.

Moreover, efficient assembly techniques can be provided that substantially reduce the time and effort required for assembly. One such technique can include coordinating the installation of a number of internal components in such that securing one component can have the effect of securing all of the components. For example, portable computing device 100 can include a main printed circuit board (referred to as a highway board) that can extend substantially across the length of portable computing device 100. In this way, the main printed circuit board can connect internal components that are disparately located within housing 102 without the need for long connectors. Moreover, by judiciously selecting those components to attach to the main printed circuit board and in what order can greatly simplify the assembly process. For example, connector assembly 124 and a main logic board, or MLB, can be mounted but not yet secured to the main printed circuit board in such a way that securing connector assembly 124 to the main printed circuit board has the effect of simultaneously securing the MLB. In this way, a single act of securing the connector assembly secures both the MLB and the main printed circuit board thereby eliminating a number of separate securing operations.

FIGS. 3-9 illustrate the operational components of portable computing device 100. The operational components are organized in layers. The relationship and organization of the operational components within each layer and the relationship between layers can be used to facilitate both the assembly and optimization of the Z stack of the internal components of portable computing device 100. In this way, minimizing the Z stack, portable computing device 100 can be extremely compact, sturdy, aesthetically pleasing and ergonomic at relatively low cost.

FIG. 3 presents a top level internal view 300 of portable computing device 100 showing a specific arrangement of various internal components. In one embodiment, the internal components can include at least battery assembly 302. Battery assembly 302 can include at least two battery cells 304, 306 supported by battery frame 308. In the described embodiment, first protective layer 310 can be wrapped around and attached to battery frame 308. First protective layer 310

12

can provide protection to battery cells 304 and 306. In some cases, first protective layer 310 can be formed of resilient yet durable material such as Mylar™ having an adhesive layer. Battery cells 304 and 306 can be attached to first protective layer 310 using the adhesive. In this way, battery cells 304 and 306 can be suspended from first protective layer 310 leaving a space between a lower surface of the battery cells 304 and 306 and interior surface 218 of housing 102. This space (which can be referred to as a swell gap) can be sized to accommodate any swelling of battery cells 304 and 306 that typically occurs during battery powered operation of portable computing device 100. It should be noted that in addition to first protective layer 310, a second protective layer can be applied to the lower surface of battery cells 304 and 306 using an adhesive, for example. The second protective layer can provide protection to battery cells 304 and 306 especially in those cases where steps 216 (or at least the steps in the vicinity of the lower surface of battery cells 304 and 306) are not rounded or otherwise shaped to avoid sharp edges. In the described embodiments, the second protective layer can be formed of any number of suitable materials that can include, for example, polyetheretherketone otherwise known as PEEK. Battery frame 308 can be shaped to conform to step patterns formed in housing 102. In this way, battery frame 308 can be mounted directly to housing 102 using selected mounting steps. In this way, battery frame 308 does not require special machining or other extraneous processing to be mounted to curved interior surface 218 of housing 102.

The internal components can include main logic board 312 that can include a number of operational circuits such as a processor, graphics circuits, (optional) RF circuitry, semiconductor memory, such as FLASH, and so on. MLB 312 can receive power from battery assembly 302 by way of electrical connectors. In one embodiment, MLB 312 can be supported, in part, by battery frame 308. The internal components can also include main printed circuit board (mPCB) 314 connected to MLB 312 by way of board to board connector 316. In the described embodiment, board to board connector 316 can include a suitable number (such as 70) of pins to provide an adequate number of communication channels between MLB 312 and other circuits in portable computing device 100. In order to facilitate communication between MLB 312 and other circuits in portable computing device 100, mPCB 314 can provide appropriate interconnection resources for MLB 312. The interconnection resources provided by mPCB 314 can include a number of electrical traces formed of conductive material incorporated into a substrate of rigid material. In order to reduce the impact on the Z stack height of the internal components, mPCB 314 can be supported in part by battery frame 308 in such a way that at least some of the vertical extent of mPCB 314 is below a top surface of protective layer 310. Furthermore, in order to protect other circuits, such as a display panel that can flex (which can be as much as 0.5 mm) in response to an external applied force (such as a user's finger pressing on cover glass 106), protective layer 318 can be adhered to a top surface of mPCB 314.

The internal components can include speaker module 320 that can include audio circuits arranged to provide an audio signal to audio drivers 322 and 324. Audio drivers 322 and 324, in turn, can provide audible output to speakers 120. Wireless circuit 326 can be mounted directly to an underside of mPCB 314 thereby using space that would otherwise go unused in a more efficient manner. In this way, the overall component density can be enhanced while at the same time reducing the number of interconnects used (since wireless

13

circuit 316 is connected directly to mPCB 314). Portable computing device 100 can also include a number of antennae used for both transmission and reception of RF energy. For example, first (logo) antenna 328 (shown in dotted line form) can be incorporated into opening 202 and, in some embodiment, be embedded in a logo, the logo being incorporated into housing 102. Second antenna 330 can be placed in a position such that a portion can be incorporated into seal 108 for better overall reception/transmission. Integrated audio module 332 can include audio circuit 334 and microphone module 336 in a compact and integrated assembly. In the described embodiment, integrated audio module 332 can provide both audio output by way of audio jack 338 and receive audio input by way of microphone 340.

In some embodiments, portable computing device 100 can support a number of different wireless standards. For example, in those cases where portable computing device 100 supports a particular wireless standard (such as the 3G standard), portable computing device 100 can include wireless circuitry appropriate for the particular wireless standard. For example, if portable computing device 100 is 3G compliant, the MLB 312 can include 3G wireless circuitry coupled to an appropriately placed and sized RF antenna (It should be noted that as discussed in co-pending U.S. patent application "HANDHELD COMPUTING DEVICE" by Ternus et al. a portion of housing 102 is typically replaced with a radio transparent window in co-operation with the RF antenna). Flex connector 342 can connect integrated audio module 332 to MLB 312 whereas display bus 344 can connect display driver circuitry to MLB 312 by way of display connector 346. In the described embodiment, display bus 344 can take the form of a low voltage differential signaling, or LVDS, bus. Bus 348 can include signal lines for coupling MLB 312 to power switch 114, mute button 116 and volume switch 118 and connector 350 can carry audio signals to speakers 120.

FIG. 4A shows an exploded view of battery assembly 320 in accordance with the described embodiments. Battery assembly 320 can include battery frame 402 onto which can be mounted circuit 404. Circuit 404 can include battery regulation and safety circuits arranged to protect battery assembly 302 from any number of operating excursions that could cause damage to battery assembly 320. Circuit 404 can also include connectors used to provide power from battery assembly 302 to MLB 312. As a safety circuit, circuit 404 can provide a fuse type circuit that prevents battery assembly 302 from overheating. Circuit 404 can be placed onto battery frame 402 within cavity 406. Battery cells 408 and 410 can be surrounded by first protective layer 412 on a top portion and second protective layer 414 adhered to a bottom portion of each of battery cells 408 and 410. In the described embodiment, second protective layer can take the form of PEEK whereas first protective layer 410 can take the form of Mylar. Platform 416 can be used to support mPCB 314.

FIG. 4B shows a close up view of battery frame 402. Battery frame 402 can be placed directly onto housing 102 using attachment features 420 and 422 that can be shaped to conform to a nearby step pattern formed in housing 102. In this way, battery frame 402 can be attached directly to housing 102 using adhesive, such as epoxy, without requiring special machining. Once securely mounted to housing 102, battery frame 402 can be used to mount other components within portable computing device 100. For example, MLB 312 can be supported by MLB support 424 whereas mPCB 314 can be placed on platform 426 and secured using

14

attachment features 428. Bosses 430 can be used to attach other components (such as speaker module 320) to housing 102.

FIG. 5 shows cross section 500 along line AA of FIG. 3 bisecting battery assembly 302, logo 502 and mPCB 314. In particular, cross section 500 illustrates compact nature of the assembled internal components. For example, logo 502 can encompass an RF antenna (referred to as a logo antenna) supported by antenna carrier 504. In order to avoid unnecessary interference with RF transmissions from the logo antenna, logo 502 can be formed of radio transparent material such as plastic, glass, ceramic and so on. However, in order to prevent the logo antenna from interfering with the operation of RF sensitive circuits within portable computing device 100 (and vice versa) and to therefore limit electronic noise, antenna carrier 504 can be formed of a radio-opaque material (such as a grounded metal sheet) that can be placed over and completely surround the logo antenna. In so doing, a substantial portion of any RF energy that backscatters from the logo antenna can be prevented from interfering with RF sensitive circuits. Display module circuit 506 can be connected to LVDS bus 344 by way of connector 346 and be used to drive display panel 508.

FIG. 6 shows a representative cross section of logo 600 in accordance with the described embodiments. As shown, logo 600 can be formed of glass, or similar material, mounted by way of adhesive 602 (such as PSA) to substrate 604. In this way, the esthetic look of logo 600 can be enhanced due to transparent or near transparent nature of the glass used to fabricate logo 600. In some cases, the glass can facilitate the transmission of light emanating from portable computing device 100. It should also be noted, that due at least to the presence of adhesive 604, any impact to logo 600 will likely only result in the cracking of glass of logo 600 with little or no shattering.

FIG. 7 shows exploded view of integrated audio module 700 in accordance with the described embodiments. Integrated audio module 700 includes audio circuit 702 and microphone module 704 enclosed within sealing boot 706. Both audio circuit 702 and microphone module 704/sealing boot 706 are incorporated onto audio module flex 708 connected to MLB 312 by way of board to board connector 710. By incorporating audio circuit 702 and microphone module 704 onto audio module flex 708, microphone port 712 (part of sealing boot 706) and audio jack 714 can be placed in close proximity to one another in housing 102. In the described embodiment, microphone port 712 can be approximately 1 mm in diameter.

The portable computing device 100 can include one or more button assemblies by which the user of the portable computing device 100 can activate various functions. Button assemblies can be mounted through the surface of the cover glass 106 of the display in the portable computing device 100 or through a front, side or back portion of the single piece housing 102 of the portable computing device 100. The button assemblies can be designed to provide a desired tactile feedback to the user when activating the button assembly's function. In addition, the button assemblies can be designed, in conjunction with designs of both outer surfaces of and inner connection points within the portable computing device 100, to be positioned approximately flush with the outer surfaces in neutral, "non-depressed" state, even with internal circuit boards located at a distance from a top portion of the button assembly.

FIG. 8A illustrates a first cross-sectional perspective view 800 and FIG. 8B a second cross-sectional view 850 of a home button assembly 802 mounted through cover glass 106

15

of a portable computing device **100** in accordance with the described embodiments. The home button assembly **802** can include an external flat or curved button body **112** that rests approximately flush with an exterior surface of cover glass **106**. Side flanges **804** can be mounted on the underside of (or integrally formed with) the external button **112** and extend beneath the underside of cover glass **106**. A central post **806** can also be mounted to the underside of (or be integrally formed with) the external button body **112** positioned above a tactile switch unit **808**. In a neutral, “non-depressed” state the central post **806** can be at a distance from the tactile switch unit **808**. Upon depressing the external button body **112**, the central post **806** can contact the tactile switch unit **808** in a manner that results in closing a contact circuit within the tactile switch unit **808**. The use of the tactile switch unit **808** can allow a user of the portable computing device **100** to experience a different “feel” when pressing at different locations on the surface of the external button body **112**, as the external button body **112** can pivot about the top of the tactile switch unit **808**.

The internal components of the portable computing device **100** can include a printed circuit board **818** through which signals can be conducted as a result of depressing the external button **802**. As illustrated in FIG. 8A, the printed circuit board **818** can be located at a distance from contact points of the tactile switch unit **808**. The distance can be such that the tactile switch unit **808** cannot be mounted directly on the printed circuit board **818**, as the travel distance of the center post **806** of the external button body **112** can be too short to reach the tactile switch unit **808** when depressed to activate a function. The printed circuit board **818** can also include components in a region directly beneath the external button body **112** that preclude mounting the tactile switch unit **808** directly to the printed circuit board **818**. Instead a connection can be made between the printed circuit board **818** and the tactile switch unit **808**.

As shown in FIGS. 8A-B, the tactile switch unit **808** can be mounted to an intermediate printed circuit board **810**. In some implementations, the intermediate printed circuit board **810** can be connected to the printed circuit board **818** through a flexible cable; however, such a connection can complicate the assembly process. In some embodiments, the flexible cable connection can preclude a simple machine automated assembly and require manual assembly by a technician. The representative embodiment shown in FIGS. 8A-B avoids manual assembly by enabling a connection from the intermediate printed circuit board **810** to the printed circuit board **818** through a pair of conductive posts **814/816** and a pair of conductive pads **812/813**. A first conductive post **814**, for example, can be connected to a DC power level supplied through the printed circuit board **818**, while the second conductive post **816** can be connected to a GND level in the printed circuit board **818**. Conductive posts **814** and **816** can be connected to separate conductive pads **812** and **813** respectively mounted on the underside of the intermediate printed circuit board **810**. Depressing the external button body **112** can close a circuit within the tactile switch unit **808** connecting the first conductive post **814** to the second conductive post **816** and thereby permitting current to flow, which can activate directly or indirectly a function of the portable computing device **100**. In addition to providing a conductive path, the conductive posts **814/816** can be sized and positioned between the intermediate printed circuit board **810** and the printed circuit board **818** to “tune” the tactile feel of the button assembly **802** for the user of the portable computing device **100**. For example, the conductive posts **814/816** can be positioned closer together

16

or further apart, and the thickness of the intermediate printed circuit board **810** can be varied to increase or decrease flexing that can occur when depressing the external button **802** to contact the tactile switch unit **808**.

As shown in FIGS. 8A-B the intermediate circuit board **810** to which the tactile switch unit **808** mounts can be covered in certain regions by a stiffener section **820**. The stiffener section **820** can be shaped to include vertical walls that prevent the flanges **804** underneath the external button body **112** from moving laterally in one or more directions and also from rotating clockwise or counterclockwise, thereby stabilizing the external button body **112** when pressed by the user. FIG. 8C illustrates a simplified top view of the home button assembly with the flanges **804** extending from underneath the external button body **112**. The top of the external button body **112** can include directional markers **822** that can assist a user in locating the external button body **112** as well as guide the user into applying pressure at appropriate locations on the external button body. The directional markers **822** can take different forms including tactile raised dots and compass point (for example north (N) and south (S)) markers. During operation of the portable computing device **100**, the user can apply pressure off center on the surface of the home button body **112**. In some embodiments, the home button body **112** can incur an unacceptably high probability of “sticking” when a top portion of button body **112** or flanges **804** can “dive under” a portion of a stiffener section **826**. For example, by pressing at the “S” end of the external button body, an edge of the anti-rotation ring **824** can catch beneath an adjacent stiffener section. To prevent such “diving”, a flexure **824** can be attached (such as by a pressure sensitive adhesive) at a first end **828** to the bottom surface of the button body **112** or flanges **804** and at a second end **830** to a surface of a nearby portion of the stiffener section **820**. The flexure can allow vertical movement of the external home button **112** but resist lateral horizontal movement of the external button body **112** and also prevent rotation along any axis, thereby preventing the external button body **112** from diving under the adjacent portion of stiffener section **826** and moving essentially in a z-direction perpendicular to the surface of the portable media device **100**.

Button assemblies can also be mounted through a portion of the single piece housing **102** that encloses the portable computing device **100**. As the single piece housing **102** can be relatively thin to reduce weight of the portable computing device **100**, openings in the housing **102** can impact the structural integrity of portions of the housing **102** near the opening. For relatively large openings, a structural support section can be included inside the housing **102** to improve rigidity; however, a button assembly can still require access through the structural support section. It can be desirable to minimize the size of openings through the structural support section, thereby retaining a desired strength of structural support, when using a relatively larger exterior button that can use a relatively larger opening in the housing **102**.

FIG. 9A illustrates an interior perspective view **900** of a housing **102** of a portable computing device **100** that includes openings for button assemblies and a structural support section **904**. As shown in FIG. 9B a relatively large external opening **922** through the housing **102** can be substantially larger than the openings **906** through the structural support section **904**. Some openings through the housing **102**, such as opening **910**, can be sized sufficiently small that a structural support section is not required, while larger openings such as opening **922** can require additional structural support. The structural support section **904** can include

17

mounting holes **908** to which a retention bracket can be secured and retain an external button mounted through the housing **102** and structural support section **904**. The structural support section **904** can be attached to housing **102** using an epoxy adhesive or by welding or by other appropriate means. FIGS. **9C** and **9D** illustrate exploded internal and external views respectively of a button assembly with the relatively large opening **922** in the housing **102** augmented by the structural support section **904**. An external volume button **118** can include two posts **934**, each post **934** having a stem portion **936** connected to the back side of the external volume button **118** and a capture portion **938**, wider than the stem portion **936**, which can contact a tactile switch mounted inside the housing **102**. In a representative embodiment, the external button **932** can be a "volume" button that can be depressed in two directions to activate two different functions such as "louder" and "softer" by contacting two separate tactile switches.

As shown in FIG. **9C**, a smaller button, for example the mute button **116**, can be mounted from the inside of the housing **102** as the opening **910** through which the mute button **116** extends is sufficiently large to accommodate the external sections of the mute button **116** while not affecting the structural integrity of the housing **102**. The volume button **118**, however, cannot be mounted from the inside of the housing **102**, as the structural support section **904** partially blocks the opening **922** for the external section of the volume button **118**. Instead volume button **118** can be mounted from outside of the housing **102**. Two openings **906** in the structural support section **904** can be sized appropriately to pass the capture portion **938** of the posts **934** on the button **932** through. After inserting volume button **118** through the housing **102**, a retention bracket **940**, which includes relatively narrow slots **946** sized according to the diameter of the stem portion **936** of the posts **934**, can be inserted to capture and retain volume button **118** securely in the housing **102**. The capture portion **938** of the posts **934** on volume button **118** can contact tactile switches mounted on a printed circuit board **942** placed behind the retention bracket. The printed circuit board **942** and the retention bracket **940** can include mounting holes through which they can be secured by fasteners to holes **908** in the structural support section **904**.

The button assembly shown in FIGS. **9A-D** enables the relatively large volume button **118** to be mounted securely through relatively large hole **922** in housing **102** and to contact a pair of tactile switches mounted inside, while also including structural support of the housing **102** around the opening **922**. Structural support integrity of the combination of the housing **102** and the structural support section **904** can be retained by using this "outside to inside" button assembly. FIG. **9E** illustrates a simplified horizontal cross-sectional view of a portion of the button assembly of FIGS. **9A-D** when assembled together. A post **934** of the volume button **118** extends through opening **922** in housing **102** and also through the narrowing opening **906** in structural support section **904**, sized to allow passage of the capture portion **938** of the post **934**. The retention bracket **940** surrounds the stem portion **936** of the post **934** and holding the post **934** of the volume button within the button assembly as the opening in the retention bracket **940** can be narrower than the diameter of the capture portion **938**. The capture portion **938** of the post **934** can contact a tactile switch **962** mounted on printed circuit board **942** when the user presses on the exterior of volume button **118**. Printed circuit board **942** and

18

retention bracket **940** can be secured to structural support section **904** by fasteners **964** through holes (as shown in FIGS. **9C-D**) therein.

FIG. **10** illustrates a flow diagram describing process **1000** for assembling internal components for a portable computing device in accordance with the described embodiments. Process **1000** begins at **1002** by receiving housing suitable for enclosing and supporting internal components of the portable computing device. The components can include, for example, a battery assembly, a main printed circuit board, a main logic board, and so on. In the described embodiment, the housing includes a plurality of mounting steps formed on interior bottom surface of the housing. The mounting steps can be formed in the housing using any well known machining operation. The steps can have a step height suitable for providing a good mounting surface for the internal components. In addition to providing a good mounting surface, the housing material removed to form the plurality of steps substantially reduces the weight of the housing with adversely affecting the structural integrity of the housing. Once the housing has been received at **1004**, the component can be inserted into the cavity at **1006** and placed in direct contact with the interior surface of the housing at **1008** using the mounting steps. In this way, the mounting feature can be mounted directly to the interior surface of the housing. Once placed directly onto the interior surface of the housing, the component can be attached to the housing at **1010** using any well known attaching process such as epoxy, welding, and so on.

FIG. **11** shows an embodiment of SIM card release mechanism **1100** in accordance with the described embodiments. SIM card release mechanism **1100** can include tray **1102** suitable for securing a SIM card when placed thereon. Push rod **1104** can be connected to ejection mechanism **1106** connected to a back portion of tray **1102**. In order to eject a SIM card (or to make tray **1102** available for placing of a SIM card) a user can apply a force to push rod **1104**. The applied force can be transferred by push rod **1104** to ejection mechanism **1106** that can pivot about pivot point **1108**. By pivoting about pivot point **1108**, ejection mechanism **1106** causes tray **1102** to move in a direction that exposes **1102** making it suitable for the user to either remove/replace or add a SIM card to tray **1102**. FIG. **12** shows SIM card release mechanism **1100** included in portable computing device **100** in a particular embodiment.

The various aspects, embodiments, implementations or features of the described embodiments can be used separately or in any combination. Various aspects of the described embodiments can be implemented by software, hardware or a combination of hardware and software. The described embodiments can also be embodied as computer readable code on a computer readable medium for controlling manufacturing operations or as computer readable code on a computer readable medium for controlling a manufacturing line. The computer readable medium is any data storage device that can store data which can thereafter be read by a computer system. Examples of the computer readable medium include read-only memory, random-access memory, CD-ROMs, DVDs, magnetic tape, optical data storage devices, and carrier waves. The computer readable medium can also be distributed over network-coupled computer systems so that the computer readable code is stored and executed in a distributed fashion.

The foregoing description, for purposes of explanation, used specific nomenclature to provide a thorough understanding of the invention. However, it will be apparent to one skilled in the art that the specific details are not required

19

in order to practice the invention. Thus, the foregoing descriptions of specific embodiments of the present invention are presented for purposes of illustration and description. They are not intended to be exhaustive or to limit the invention to the precise forms disclosed. It will be apparent to one of ordinary skill in the art that many modifications and variations are possible in view of the above teachings.

The embodiments were chosen and described in order to best explain the principles of the invention and its practical applications, to thereby enable others skilled in the art to best utilize the invention and various embodiments with various modifications as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the following claims and their equivalents.

While the embodiments have been described in terms of several particular embodiments, there are alterations, permutations, and equivalents, which fall within the scope of these general concepts. It should also be noted that there are many alternative ways of implementing the methods and apparatuses of the present embodiments. For example, although an extrusion process is preferred method of manufacturing the integral tube, it should be noted that this is not a limitation and that other manufacturing methods can be used (e.g., injection molding). It is therefore intended that the following appended claims be interpreted as including all such alterations, permutations, and equivalents as fall within the true spirit and scope of the described embodiments.

What is claimed is:

1. A button assembly for a portable electronic device having a housing and a button aperture, the button assembly comprising:

a single piece button body having a first post and a second post extending from opposite ends of the single piece button body;

a first structural member having first and second openings, the first structural member being contained within the housing coupled to an internal side of the housing at the button aperture to form a housing recessed area;

a second structural member having third and fourth openings, the third and fourth openings engaging the first and second posts to couple the first and second structural members together; and

a first tactile switch and a second tactile switch aligned with the first and second posts, wherein the single piece button body is configured such that the first post independently contacts the first tactile switch when a first force is applied to the button body at the end of the first post, the second post independently contacts the second tactile switch in response to when a second force is applied to the button body at the end of proximate the second post, and both the first post and second post simultaneously contact the first and second tactile switches when a third force is applied to the single piece button body across both the first post and second post.

2. The button assembly as recited in claim 1, wherein the first structural member is fastened to the housing of the electronic device one of by welding, epoxy or adhesive.

3. The button assembly as recited in claim 2, wherein the single piece button body is at least partially disposed within the recessed area.

4. The button assembly as recited in claim 3, wherein the single piece button body is complimentary shaped with the aperture.

20

5. The button assembly as recited in claim 3, wherein the second structural member reinforces the housing of the electronic device proximate to the recessed area.

6. The button assembly as recited in claim 1, further comprising a printed circuit board coupled to the second structural member, wherein the printed circuit board is coupled to the first and second tactile switches.

7. The button assembly as recited in claim 1, wherein the third and fourth openings are slots that extend to an edge of the second structural member.

8. The button assembly as recited in claim 7, wherein the first and second posts each have stem portions having a cylindrical shape with a first diameter and capture portions having a cylindrical shape with a second diameter.

9. The button assembly as recited in claim 8, wherein the first diameter is less than a width of the slots forming the third and fourth openings and the second diameter is greater than the width of the slots forming the third and fourth openings.

10. An electronic device comprising:

a housing enclosing one or more electronic components; a large opening in the housing;

a reinforcing plate coupled to an interior surface of the housing and covering the large opening, the reinforcing plate having first and second openings wherein the large opening and the reinforcing plate cooperate to form a depression in the housing

a single piece button body disposed in the depression;

a first post and a second post extending from the single piece button body, wherein the first post protrudes through the first opening and the second post protrudes through the second opening;

a retention bracket disposed along an interior surface of the housing and having a third opening and a fourth opening, wherein the first and second posts protrude through the third and fourth openings and the single piece button body is coupled to the electronic device by the retention bracket; and,

a first tactile switch and a second tactile switch aligned with the first and second posts, wherein the single piece button body is configured such that the first post independently contacts the first tactile switch when a first force is applied to the button body at the end of the first post, the second post independently contacts the second tactile switch in response to when a second force is applied to the button body at the end of proximate the second post, and both the first post and second post simultaneously contact the first and second tactile switches when a third force is applied to the single piece button body across both the first post and second post.

11. The electronic device as recited in claim 10, wherein exerting a force on a first end of the single piece button body causes the electronic device to perform a first electrical function, exerting a force on a second end of the single piece button body causes the electronic device to perform a second electrical function, and exerting the third force causes the electronic device to perform a third electrical function.

12. The electronic device as recited in claim 11, wherein the first electrical function raises a volume level of the electronic device and the second electrical function lowers the volume level of the electronic device.

13. The electronic device as recited in claim 12, wherein the electronic device is a tablet computer.

14. The electronic device as recited in claim 12, wherein the third and fourth openings are slots that extend to a lower edge of the retention bracket, the slots allowing the retention

21

bracket to be placed in position and retain the single piece button body after the first and second posts are inserted through the first and second openings in the housing.

15 15. The electronic device as recited in claim 14, wherein the reinforcing plate and retention bracket cooperate to provide structural stiffness to the housing in an area surrounding the large opening in the exterior layer of the housing.

10 16. The electronic device as recited in claim 14, further comprising at least one flange extending from the retention bracket, wherein the at least one flange is coupled to a printed circuit board including the first and second tactile switches.

15 17. The electronic device as recited in claim 16, wherein first and second posts are formed integrally with the single piece button body.

20 18. A button assembly for receiving a user input to an electronic device having a housing having a recess, comprising:

a single piece button body disposed within the recess and comprising a first distal end and a second distal end, the single piece body comprising:

25 a first stem portion aligned with a first tactile switch and comprising a first post directly aligned with the first distal end that extends away from an interior surface of the single piece button body along a first axis and that terminates at a first capture portion that is larger than the first post, and

22

a second stem portion aligned with a second tactile switch and comprising a second post directly aligned with the second distal end that extends away from the interior surface of the single piece button body along a second axis and terminates at a second capture portion that is larger than the second post; and

a retention member secured to an interior of the housing and having a first opening aligned with the first axis and being larger than the first post and narrower than the first capture portion and a second opening aligned with the second axis being larger than the second post and narrower than the second capture portion, wherein when a force is applied to the single piece button body at the first distal end, the force is directed along the first axis such that the first stem portion pivots about the second axis that acts as a first fulcrum for actuating the first tactile switch.

19. The button assembly of claim 18, wherein when a second force is applied to the single piece button body at the second distal end, the second force is directed along the second axis such that the second stem portion pivots about the first axis that acts as a second fulcrum for actuating the second tactile switch.

20. The button assembly of claim 19, wherein when a third force is applied to the single piece button body across the second distal end and the first distal end, the third force is directed along both the second and first axis actuating both the first and second tactile switch.
